Introduction

Poly Methyl Methacrylate (PMMA) is the positive tone resist and it is most popular and promising resist for very high resolution patterns in electron beam lithography. It is available with different solvents with many concentrations. In the present work various high resolution e-beam patterns are optimised using PMMA 950KA4 (Molecular weight:950K, A: Anisole solvent, Resist Concentration: 4%) and mainly focused on area lines optimization at various resolutions using different EHT.

Objectives

1. To understand the optimum electron dose for various high resolution patterns in electron beam lithography
2. To investigate the impact of electron beam dose on critical dimensions at different EHT voltages

Experimental details

E-Beam Lithography exposures is carried out in Raith PIONER system. PPMA950KA4 resist spin coated on Si wafer with the speed of 6000rpm for 45 seconds and thickness is about 180 to 200nm. Sample is prebaked on hot plate at 170°C for 120 seconds. Area lines of different width and different spacing are exposed at 10kV, 20kV and 30kV EHT using 20μm aperture. Some specific high resolution patterns like squares, hexagon structures and circles optimised using 20kV EHT with 10μm aperture. After e-beam exposure, samples are developed in MIBK: IPA (1:3) developer for 45seconds and 15sec dip in stopper(IPA). Impact of electron beam dose on critical dimensions is studied and plotted as shown in Figure.3 and Figure.4.

Results and discussion

Optimization of Area mode line patterns:
The Critical dimensions(CD) using 20kV and 30kV EHT are optimized and shown in below figures and CD Vs Dose results are shown in Figure.3&4.
High resolution patterns at 10kV EHT are much broader than the targeted feature size, some features are completely merged. At 20kV EHT patterns are little broader than the targeted critical dimensions even at the optimum electron dose, see figure 1 and 2. At lower electron doses, patterns are underexposed, then pattern width increases from the optimum electron dose to higher dose. Some of targeted critical dimensions are achieved using 30kV EHT. This could be due to the penetration of electron beam through the resist with less scattering at higher EHT. Impact of EHT on critical dimensions is shown in figure 7.

Same critical dimensions with different spacing have different optimum electron doses. As shown in figure 3, the optimum electron dose for L/S = 60/60 is ~160µC/cm² and for L/S = 60/120 is ~195µC/cm². This variation in dose could be due to the proximity effect. The optimum dose for L/S = 60/60 pattern at 20kV EHT is ~160µC/cm² and the optimum dose for L/S = 60/60 pattern at 30kV EHT is ~220µC/cm². This indicates that the optimum dose for a pattern varies with EHT. This is also due to less scattering at higher EHT. Higher dose is required to cover the targeted feature at higher EHT.

Optimization of other typical E-Beam lithography patterns:

Other than the area line patterns, some of other typical high resolution structures like squares, circles and hexagons are optimized. Dimensions and patterning parameters are tabulated below. Circles can be patterned by two exposure methods, one is area mode exposure another one single pixel dot exposure method. Among the two methods, single pixel dots can give minimum features compared to area mode circles.
A) High resolution Hexagon structures

B) Circles using single pixel dot exposure

C) Circles using single pixel dot exposure

D) Square patterns

E) Area mode circles

F) Area mode lines

Figure 8: Typical optimised e-beam lithography patterns
Area mode exposure circles will have smoother curves than the single pixel dot exposure circles. In area mode exposure, multiple beam incidence occurs on ER coated substrate to pattern/cover the feature as per the design. Each single ebeam spot causes some scattering around the spot, Consequently more resist area than the required feature can be defragmented. So that the feature size will be more than the actual design. This can be avoided by using higher EHT with lower aperture to achieve minimum features with smoother edges.

**Conclusion**

In this document, we showed our recent optimization activities to achieve high resolution e-beam lithography patterns using PMMA950kA4 resist and studied the influence of EHT voltage and exposure dose on high resolution patterns. Parameters are optimized for critical dimensions like L/S:60nm/60nm and also
for different kind of structures. We will continuously been improving the patterns quality such as line edge roughness control and proximity effect control.
